

Competence Checkpoint

During this lecture you will work independently to produce your own [animation demo](#).

Using the sprite-sheet below, you will each write a program that

- integrates the provided code, specifically `class Animation` (based on the one we develop together last class), a `main.py` and `class Game` with your own `class Player` and
- uses a state-machine of your own design that defines the states and transitions of the character.

Planning: state machine

As the one displayed above, design below your own state-machine that you will guide your code, using the different rows of the sprite sheets above.

You must at least have three states and one of each `AnimationType` (i.e. one repeating, one one shot)

Note that my demo **does not include jumping** as my first attempt was to keep the code simplest.

Keep it simple is key to a quick and successful development; hence demonstrating your competence.

Coding

There are two ways to run the provided code

1. a `def test` is provided in `class Animation` and
2. the `main` of `main.py`

Your task is to incrementally develop code that works and follows good style. Again remember less is more: completing two states is better than having unused code that does not apply to the task at end and no states actually working.

This exercise aims to demonstrate your mastery of the concepts we are learning to code in this class.

You may use your notes, any code we used in class and online documentation of python and `raylib`. You may refer to the [design pattern chapter](#) if your notes are insufficient.

You should understand all the code you submit. **You should not use AI.**

Roadmap to fill

Your name: _____

Document each small problem you are working on, before starting to code
